Mavera

Mavera turns a paid API into shares; every x402 call pays the holders within one Monad block.

A bear sells honey; every time a jar sells, coins drip into his friends' cups.

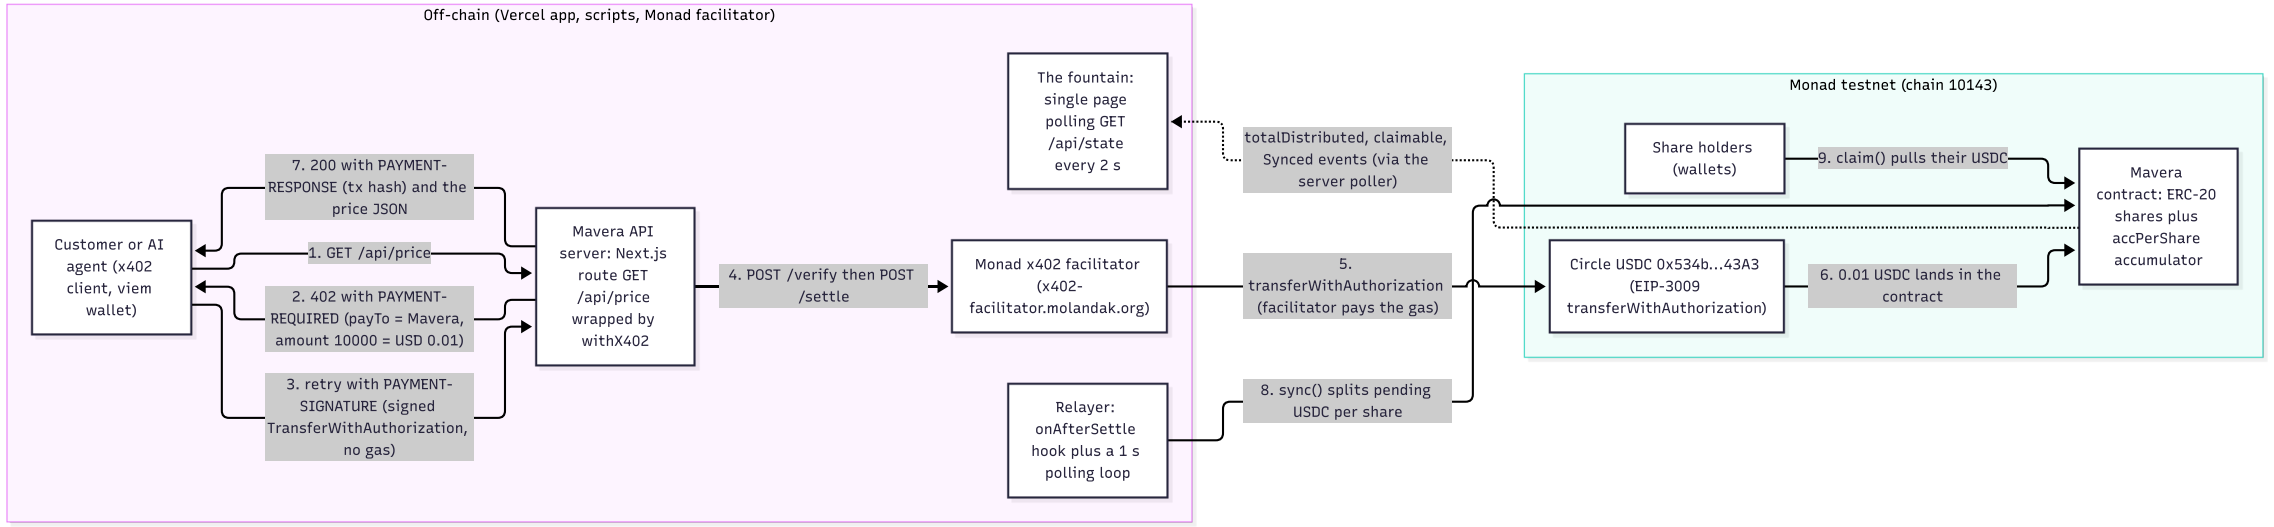

USD 0.01

per API call, in USDC, split to the share holders

Mavera · Monad Blitz Ankara v4 · 24 Oct 2026 · Monad testnet (chain 10143), Circle test USDC

How it works: one call, one block

1. Call, 402

GET /api/price answers 402 with payTo = the contract.

2. Signed payment

The client signs an EIP-3009 authorization; no gas, no account.

3. Settle

The Monad facilitator moves 0.01 USDC into Mavera and pays the gas.

4. sync, claim

sync() splits it per share; holders pull with claim().

Why Monad, and why a chain at all

- **The payer is a machine.** x402: an agent with no bank account signs a USDC authorization; the server answers 402, then 200.
- **The payee is the contract.** payTo is Mavera itself, so payment and dividend are one atomic flow; the operator never holds the revenue.
- **Sub-cent split per call is only sane here.** One distribution, sync() at a 200,000-gas limit, costs about **USD 0.0004** at the 100 MON-gwei minimum base fee: under 5% of a 1-cent call.
- **Visible in about 300 ms, final at about 600 ms.** On a 12-second chain the fountain would not move.
- **Monad runs a public x402 facilitator**, which pays the settlement gas; API Hub lists 136 pay-per-call services on mainnet today.

Sources: docs.monad.xyz (block time, gas pricing), x402-facilitator.molandak.org, app.monad.xyz/agents/api-hub, accessed 24 Oct 2026. Testnet build; mainnet would need a KYC allow-list and a licensed wrapper.

Our difference: one permissionless contract, per call

vs Stripe Connect splits: a custodial, revocable promise from the operator's bank account. In Mavera the operator never touches the money; the client refuses to pay anything but the contract.

vs revenue-share tokens that pay monthly: a company, a vault or a bond in the loop (x402commit, Bondrail). Mavera distributes every call within one Monad block, and anyone can call sync().

vs plain x402 endpoints: the operator keeps all the revenue; no shared upside. Mavera's shares are a transferable ERC-20 cash-flow claim: the only thing that moves it is customers paying.

Accounting is the ERC-1726 dividend-token pattern (2019). Of 1,759 approved Blitz projects scanned on 24 Oct 2026, none combines an x402-paid API, ERC-20 shares and per-call distribution. Testnet proof of concept with test USDC. Not an offer of securities.
